01 · Is there a Phillips-curve trade-off in Brazil? (2012–2026)

Final report generated by the pipeline (python run_all.py). Tables and figures are the pipeline's own outputs; the text comes from the paper's README.

Question

Does higher unemployment go with lower inflation in Brazil, once inflation inertia and expectations are in the model?

Result

• In the static model the unemployment coefficient is -0.002 (SE 0.010), with no stars: no static trade-off.

• In the dynamic model, lagged inflation has a coefficient of 0.398 and the Focus expectation 0.686, both significant at 1%; unemployment stays insignificant at 0.007.

• R^2 rises from 0.000 to 0.421, on 169 monthly observations.

• H0: $\gamma + \delta = 1$ is not rejected ($p = 0.432$): the data do not reject a vertical long-run Phillips curve.

• With Newey–West errors the standard error on the expectation term rises from 0.111 to 0.177; it stays significant.

• With seasonal dummies the expectation coefficient is 0.783 and R^2 0.523; without the COVID months unemployment is 0.001.

Reading: Brazilian inflation is driven by inertia and expectations; labour-market slack barely shows up. Descriptive, not causal: expectations are endogenous and the model uses the unemployment rate, not the gap to its natural rate.

Data checks

17 pass, 1 warnings, 0 fail (details in output/data_checks.json).

Main tables

Curva de Phillips: especificação estática vs. dinâmica (MQO)

	Dependent variable: IPCA mensal
